***Abstract*—This systematic literature review aimed to identify which LLM-based tools are evaluated for code generation and program repair, assess how correct and secure the code produced by LLM assistants is, and determine the measured effect of AI assistants on developer productivity. Studies were included if they empirically evaluated LLM-based code generation, repair, or developer productivity, while position papers or abstracts without empirical evaluation were excluded. Across 6 included studies published between 2021 and 2024, 6 records were screened, assessed for eligibility, and extracted for analysis without quality assessment or reported exclusion reasons. Empirical findings indicate that GitHub Copilot achieved high accuracy in code generation benchmarks, and program repair accuracy improved significantly when automated sampling was employed. Furthermore, repeated model sampling demonstrated effectiveness for code generation. However, functional correctness varies strongly by target programming language and task difficulty, reported metrics evaluated on contaminated benchmarks may be overstated, and long-term code quality was not measured in related productivity experiments. Additionally, generated code may contain security weaknesses in approximately 35% of snippets across multiple Common Weakness Enumeration categories. The findings imply that while large language models show promising capabilities, their measured effectiveness appears to remain contingent on benchmark integrity, sampling parameters, task complexity, and security considerations.

***Index Terms*—Large Language Models, Code Synthesis, Automated Program Repair, GitHub Copilot, Empirical Software Engineering, PRISMA 2020.**

I. INTRODUCTION

A. Research Questions

The primary objective of this systematic literature review is to delineate the core research questions driving current scholarly inquiry within the field. A synthesis of the extant literature indicates that contemporary investigations predominantly focus on identifying key operational challenges and evaluating the efficacy of emerging methodological frameworks.

II. SYSTEMATIC REVIEW METHODOLOGY

A. Review Questions and Scope

The review addressed the following research questions:

- RQ1: Which LLM-based tools are evaluated for code generation and program repair?
- RQ2: How correct and how secure is the code that LLM assistants produce?
- RQ3: What is the measured effect of AI assistants on developer productivity?

B. Eligibility Criteria and PICOC Elements

Studies were included if they met the following criteria:

- IC1: Empirically evaluates LLM-based code generation, repair or developer productivity.

Studies were excluded if they met the following criteria:

- EC1: Position papers or abstracts without an empirical evaluation.

The review question was framed with the PICOC elements below.

- Population: Software developers; Open-source projects
- Intervention: LLM code assistants; GitHub Copilot; Codex
- Comparison: Manual coding; Traditional repair tools
- Outcome: Functional correctness; Security weaknesses; Task completion time
- Context: Benchmarks and industrial settings, 2021-2024

C. Search Strategy and Information Sources

The databases and other sources that were searched were not reported in the review record.

D. Study Selection (PRISMA 2020 Flow)

TABLE I. PRISMA 2020 STUDY SELECTION AND SCREENING SUMMARY

Phase	Records	Excluded	Synthesis Protocol
Identification	6 records	0 duplicates	Database & Snapshot
Screening	6 screened	0 excluded	Title & Abstract (IC1/EC1)
Eligibility	6 assessed	0 unretrieved	Full-text Verification
Included	6 studies	—	Quantitative Synthesis

Records were identified from databases and registers (n = 0), from other methods (n = 0) and without a recorded source (n = 6). Before screening, 0 duplicate records and 0 records for other reasons were removed. A total of 6 records were screened and 0 were excluded. A total of 6 reports were sought for retrieval, of which 0 could not be retrieved. A total of 6 reports were assessed for eligibility. No reports were excluded after full-text assessment with a recorded reason. A total of 6 studies were included in the review.

The review record does not report the following counts: records removed by automation tools and reports of the included studies.

E. Data Extraction and Appraisal Protocol

Data were extracted for 6 of the 6 studies selected for extraction. No quality assessment was recorded for the included studies.

F. Corpus Characteristics and Demographics

The review corpus contains 6 studies, published during 2021–2024.

III. EMPIRICAL RESULTS AND SYNTHESIS

A. RQ1: Code Synthesis and Program Repair Tools

An overview of the current literature suggests that model-driven code generation and program repair performance varies across evaluation contexts and operational strategies. Specifically, empirical evidence indicates that GitHub Copilot achieved high accuracy in code generation benchmarks, while program repair accuracy improved significantly when automated sampling was employed [2], [4]. Supporting findings further indicate that functional correctness appears to depend strongly on programming language and task difficulty, repeated model sampling may serve as a surprisingly effective strategy, generated code may contain security weaknesses in roughly 35% of snippets across multiple CWE categories, and results evaluated on contaminated benchmarks might be overstated [1], [2], [4], [5]. Synthesizing these insights implies that while large language models show promising capabilities, their measured effectiveness appears to remain contingent on benchmark integrity, sampling parameters, task complexity, and security considerations.

Empirical evaluations in the primary literature detail the performance capabilities of automated code synthesis models. Specifically, an evaluation of GitHub Copilot demonstrated that the system achieved high accuracy in code generation benchmarks [2], while another study observed that program repair accuracy improved significantly with automated sampling strategies [4]. However, findings regarding functional correctness indicate that performance varies strongly depending on the target programming language and task difficulty [2], while reported outcomes on contaminated benchmarks may be overstated [4].

An examination of empirical evaluations reveals nuanced performance dynamics across code generation and program repair domains. While repeated sampling from models demonstrates considerable effectiveness in code generation tasks [1] and automated sampling appears to improve program repair accuracy [4], functional correctness still seems to vary substantially based on the target programming language and task complexity [2]. Nevertheless, these reported gains must be interpreted cautiously, as performance metrics derived from contaminated benchmarks may be overstated [4] and approximately 35% of generated snippets may still harbor security weaknesses across multiple CWE categories [5].

B. RQ2: Functional Correctness and Security Vulnerabilities

Emerging evidence suggests that large language models may enhance software engineering tasks under specific circumstances. Empirical evaluations indicate that GitHub Copilot appeared to achieve high accuracy in code generation benchmarks, while program repair accuracy seemed to improve significantly when automated sampling was employed [2], [4]. Synthetically, these findings indicate that AI-assisted tools could potentially offer measurable performance gains in automated code generation and repair workflows.

Regarding the evaluation of code generation and program repair tools, empirical studies present detailed performance evaluations across various benchmarks. Specifically, an evaluation of GitHub Copilot reported that Copilot achieved high accuracy in code generation benchmarks [2], while another study noted that program repair accuracy improved significantly with automated sampling [4]. However, these reported outcomes depend on the specific benchmark tasks and sampling strategies evaluated within each experiment.

Evaluating AI-assisted software engineering tools reveals varied outcomes across generation and repair tasks. On one hand, GitHub Copilot demonstrated high accuracy in code generation benchmarks [2], while automated sampling techniques appeared to significantly improve program repair accuracy across several benchmarks [4]. However, these performance insights may remain qualified, as long-term code quality was not measured in related productivity experiments [3].

IV. DISCUSSION AND THREATS TO VALIDITY

A. Synthesis of Agreement and Divergence

A comparative analysis of the included studies reveals key areas of convergence and conflict regarding the evaluated outcomes. Across the reviewed literature, several findings align in demonstrating consistent operational patterns, whereas other results diverge based on methodological variations. However, these synthesised insights must be contextualised within the specific parameters and constraints of the underlying primary research.

B. Threats to External and Construct Validity

This systematic literature review evaluated the current body of research according to the defined protocol. However, a primary limitation of this synthesis stems from the restricted scope and availability of the underlying primary evidence.

V. CONCLUSION AND FUTURE WORK

This systematic literature review addressed three research questions regarding large language model (LLM) tools in software engineering. Regarding RQ1, the evaluated tools identified in the included literature for code generation and program repair specifically include GitHub Copilot and OpenAI Codex.

In response to RQ2, concerning the correctness and security of the generated code, GitHub Copilot achieved high accuracy in code generation benchmarks, and program repair accuracy improved significantly when automated sampling strategies or repeated model sampling were used. However, functional correctness remains strongly dependent on the target programming language and task difficulty, and performance outcomes evaluated on contaminated

benchmarks may be overstated. In terms of security, generated code was found to contain security weaknesses in roughly 35% of snippets across multiple Common Weakness Enumeration categories. [3] [4]

Addressing RQ3, the measured effect of AI assistants on developer productivity was not established with detailed productivity metrics in the synthesised findings, as long-term code quality was not measured in related productivity experiments. Overall, the available evidence is limited by the restricted scope and availability of the underlying primary literature, as well as the absence of long-term code quality measurements in productivity evaluations.
